MEMORANDUM

TO: Warren Hansen, Regional Wildlife Manager

FROM: Adam Grove, Wildlife Biologist – Townsend

DATE: April 18, 2024

SUBJECT: Upper Missouri River spring white-tailed deer survey

An aerial white-tailed deer survey was flown in the Toston/Townsend area in the late afternoon/evening (has traditionally been felt to be the best time to observe white-tailed deer in this area) of April 12, 2024, in an FWP Supercub aircraft operated by FWP state pilot TJ Reynolds out of Dillon. The pilot stopped in Townsend to do the survey on his way back from flying mule deer surveys in Region 6.

The area surveyed included both sides of the Canyon Ferry WMA (flown last due to heavy brush cover and deer tend to come out later in the day on the WMA) and areas nearby to the south and east, both sides of the Missouri River south to Toston and then west along the Crow Creek drainage to state Hwy 437 (survey started at Hwy 437. Survey time was approximately 2.1 hrs with a total flight time of 3.4 hrs (approximately 0.3 hrs of ferry time plus 1.0 hrs pilot ferry time).

Survey conditions ranged from partly cloudy at the start to mostly cloudy by the end of the survey. Light conditions were variable and weren't the greatest by the end of the survey (clouded up more than forecasted). Winds were initially around 11-15 mph on the ground (stronger aloft) but died down to less than 10 mph as the survey progressed. Temperatures at the airport ranged from 73 to 69 degrees which was warmer than ideal. Most of the deer observed were up and out of the brush (mostly willows), while others were observed bedded or standing in the brush. Green-up conditions were fairly far along in areas down around Toston and along the Missouri River. As usual, areas on the Canyon Ferry WMA (CFWMA) were less green in part due to the excessive amounts of old herbaceous vegetation (mostly reed canary grass) in many areas of the WMA. Overall survey run quality was rated as fair to good.

A total of 331 white-tailed deer (281 adults, 50 fawns) were observed in 51 groups during the survey. This year's fawns:100 adults ratio was 17.8 which was approximately 11% above last year's ratio of 16.0. This year's ratio, while slightly better than last year's, was probably a byproduct of the hard 2022-23 winter, and its effects on fawn production and early fawn survival in the late spring of 2023. This year's ratio of 17.8 is approximately 41% below the long-term spring average of 36.0 fawns:100 adults (some variation likely due to different observers pre and post 2014). Spring fawn recruitment has been below 30 fawns per 100 adults every year but one since 2014 in the survey area.

The number of deer observed during this year's spring survey (331) is approximately 30% lower than the number observed last spring (472), and the total is approximately 8% lower than the average number observed (507) in the spring since the survey area was expanded back in

2009/10. It should be noted that survey timing, i.e. the ability to catch deer up and feeding and out of brush areas, really influences observability during this survey particularly on the Canyon Ferry WMA portion of the survey, often resulting in considerable variation in the number of deer observed annually.

Breaking the survey results down by area (Table 3), a total of only 113 (98 adults, 15 fawns) were observed along the Missouri River and Crow Creek drainages this spring compared to 204 in 2022, while 218 (183 adults, 35 fawns) were observed either on or in the vicinity of the Canyon Ferry WMA this spring compared to 268 last year. Not sure what to make of the significant difference in numbers between last year and this year particularly in the Crow Creek-Missouri River stretch, most notably along Crow Creek. It could be that with the warm weather some deer remained bedded in the willows and were just missed during the survey (survey variability issue). I haven't received any reports to indicate that we had an EHD event last year or anything, and the winter and early spring were generally very mild weather. However, a lot of the observed groups were pretty small in size (5 or less deer).

In addition to white-tailed deer, three active bald eagle nests were also observed, and one calf moose was observed on Canyon Ferry WMA during the survey.
